In 1937, Majorana gave a "symmetric theory of electrons and positrons," in which there might be no distinction between spin-1/2 particles and antiparticles. *E. Majorana, Nuovo Cimento 14, 171 (1937)*

He noted that this theory doesn't apply to charged particles like electrons and positrons, but might apply to neutrinos.

However, in a gauge theory, interacting fermions and antifermions have different quantum numbers, and cannot form Majorana states.

Charge:	Isotopic	Hyper	Electric
$d_L$	-1/2	+1/3	-1/3
$e_L$	-1/2	-1	-1
$(\nu_e)_L$	+1/2	-1	0
$u_L$	+1/2	-1/3	+2/3
$d_R$	0	+2/3	-1/3
$e_R$	0	-2	-1
$(\nu_e)_R$	0	0	0
$u_R$	0	+4/3	+2/3

In 1960, Glashow postulated a new symmetry,  $SU(2)_T \otimes U(1)_Y$ , based on weak isospin,  $T$ , and the conserved quantum numbers/charges  $T_3$  and weak hypercharge,  $Y_W = 2(Q - T_3)$ . *S.L. Glashow, Nucl. Phys. 22, 579 (1961)*

Antiparticles have the opposite quantum numbers of those in the table.

$$\bar{\nu}_R = C_W \nu_L^* \equiv \nu_L^{(C_W)}, \quad \bar{\nu}_L = C_W \nu_R^* \equiv \nu_R^{(C_W)}, \quad \text{where } C_W = \gamma^5 C \text{ is the weak-hypercharge-conjugation operator.}$$

$$= C \nu_R^* = i\gamma^2 \nu_R^* \equiv \nu_R^{(C)}, \quad = C \nu_L^* = i\gamma^2 \nu_L^* \equiv \nu_L^{(C)},$$

Recall that in the  $V - A$  theory, and in the Glashow-Weinberg-Salam electroweak theory, only the neutrino states  $\nu_L$  and  $\bar{\nu}_R$  interact (and hence cannot be members of Majorana states).

(Weak isotopic charge) = (electric charge) - 1/2 (hypercharge)

The  $\nu_R$  and  $\bar{\nu}_L$  are sterile neutrinos, and could be Majorana states. *B. Pontecorvo, Sov. J. Nucl. Phys. 26, 984 (1968)*

## Majorana Neutrino Chirality States?

Despite the incompatibility of Majorana states with Standard Model neutrinos of nonzero weak hypercharge, people consider two possibilities:

- $\psi_L = \frac{\nu_L + \nu_L^{(C_W)}}{\sqrt{2}} = \frac{\nu_L + \bar{\nu}_R}{\sqrt{2}} = \psi_L^{(C_W)}, \quad \psi_R = \frac{\nu_R + \nu_R^{(C_W)}}{\sqrt{2}} = \frac{\nu_R + \bar{\nu}_L}{\sqrt{2}} = \psi_R^{(C_W)},$  based on weak hypercharge conjugation.
- $\psi_L = \frac{\nu_L + \nu_L^{(C)}}{\sqrt{2}} = \frac{\nu_L + \bar{\nu}_L}{\sqrt{2}} = \psi_L^{(C)}, \quad \psi_R = \frac{\nu_R + \nu_R^{(C)}}{\sqrt{2}} = \frac{\nu_R + \bar{\nu}_R}{\sqrt{2}} = \psi_R^{(C)},$  based on electric charge conjugation.

Form 2 appears much more often in the literature than Form 1.

## Confrontation of Form 1, $\psi_L = \frac{\nu_L + \bar{\nu}_R}{\sqrt{2}}$ , with Experiment

If the lefthanded-chirality neutrinos that participate in the  $V - A$  weak interaction had the form  $\psi_L = \frac{\nu_L + \bar{\nu}_R}{\sqrt{2}}$ , then many existing experiments exclude this.

A good place to start is the charged-pion decay,  $\pi^+ \rightarrow \mu^+ \nu$ ,  $\pi^- \rightarrow \mu^- \bar{\nu}$ , where the muon is almost at rest in the pion frame,  $KE_\mu \approx 4 \text{ MeV}$ .

Here, a lefthanded chirality  $\mu_L^-$  (or righthanded chirality  $\mu_R^+$ ) has essentially equal probability to be either positive or negative helicity.

The pion has spin zero, a lefthanded neutrino has almost pure negative helicity, and a righthanded antineutrino has almost pure positive helicity.

Hence, a neutrino can only appear in the final state together with a negative-helicity muon (and an antineutrino can appear only with a positive-helicity muon).

If Form 1 held, there would be essentially equal rates for the two decay modes  $\pi^+ \rightarrow \mu_R^+ \nu$ ,  $\pi^+ \rightarrow \mu_L^+ \bar{\nu}$ , and also for the two modes  $\pi^- \rightarrow \mu_L^- \bar{\nu}$ ,  $\pi^- \rightarrow \mu_R^- \nu$ .

Only the first of each pair is observed in experiment!

## Confrontation of Form 2, $\psi_L = \frac{\nu_L + \bar{\nu}_L}{\sqrt{2}}$ , with Experiment

Here, the supposed Majorana neutrino states are  $\psi_L = \frac{\nu_L + (\nu_L)^C}{\sqrt{2}} = \frac{\nu_L + \bar{\nu}_L}{\sqrt{2}} = (\psi_L)^C$ ,  $\psi_R = \frac{\nu_R + (\nu_R)^C}{\sqrt{2}} = \frac{\nu_R + \bar{\nu}_R}{\sqrt{2}} = (\psi_R)^C$ .

Since the lefthanded antineutrino  $\bar{\nu}_L$  does not participate in the  $V - A$  weak interaction, there is no physical difference in single-neutrino interactions of a Dirac lefthanded neutrino  $\nu_L$  or the above Majorana state  $\psi_L$ , except for the normalization factor  $1/\sqrt{2}$ .

For Majorana states normalized with the factor  $1/\sqrt{2}$ , rates of single-neutrino interactions with a single internal  $W$  would be down by  $\frac{1}{2}$  compared to those for Dirac neutrinos.

Can fix this by multiplying the electroweak coupling constant  $g$  by  $\sqrt{2}$ .

But, then should also multiply  $g'$  by  $\sqrt{2}$  to keep the Weinberg angle  $\theta_w = \tan^{-1} g'/g$  the same, which would increase the predicted decay width of the  $Z^0$  by  $\sqrt{2}$ , in disagreement with experiment by 200%.

Existing data exclude both forms of light Majorana neutrino states!

Experimental data on the  $W$  and  $Z$  were not yet available in the 1970's, when the see-saw mechanism with Majorana neutrinos was developed to explain the low mass of observed neutrinos. *H. Fritzsch, M. Gell-Mann and P. Minkowski, Phys. Lett. B 59, 256 (1975)*
