

**Bunch-Timing Measurement
in the Muon Cooling Experiment
Via $\text{TE}_{0,1,n}$ RF Cavities**

Consider a $\text{TE}_{0,1,n}$ cavity of length a , height a/α and peak field parameter

$$\eta = \frac{eE_0}{m\omega c} = 0.0223,$$

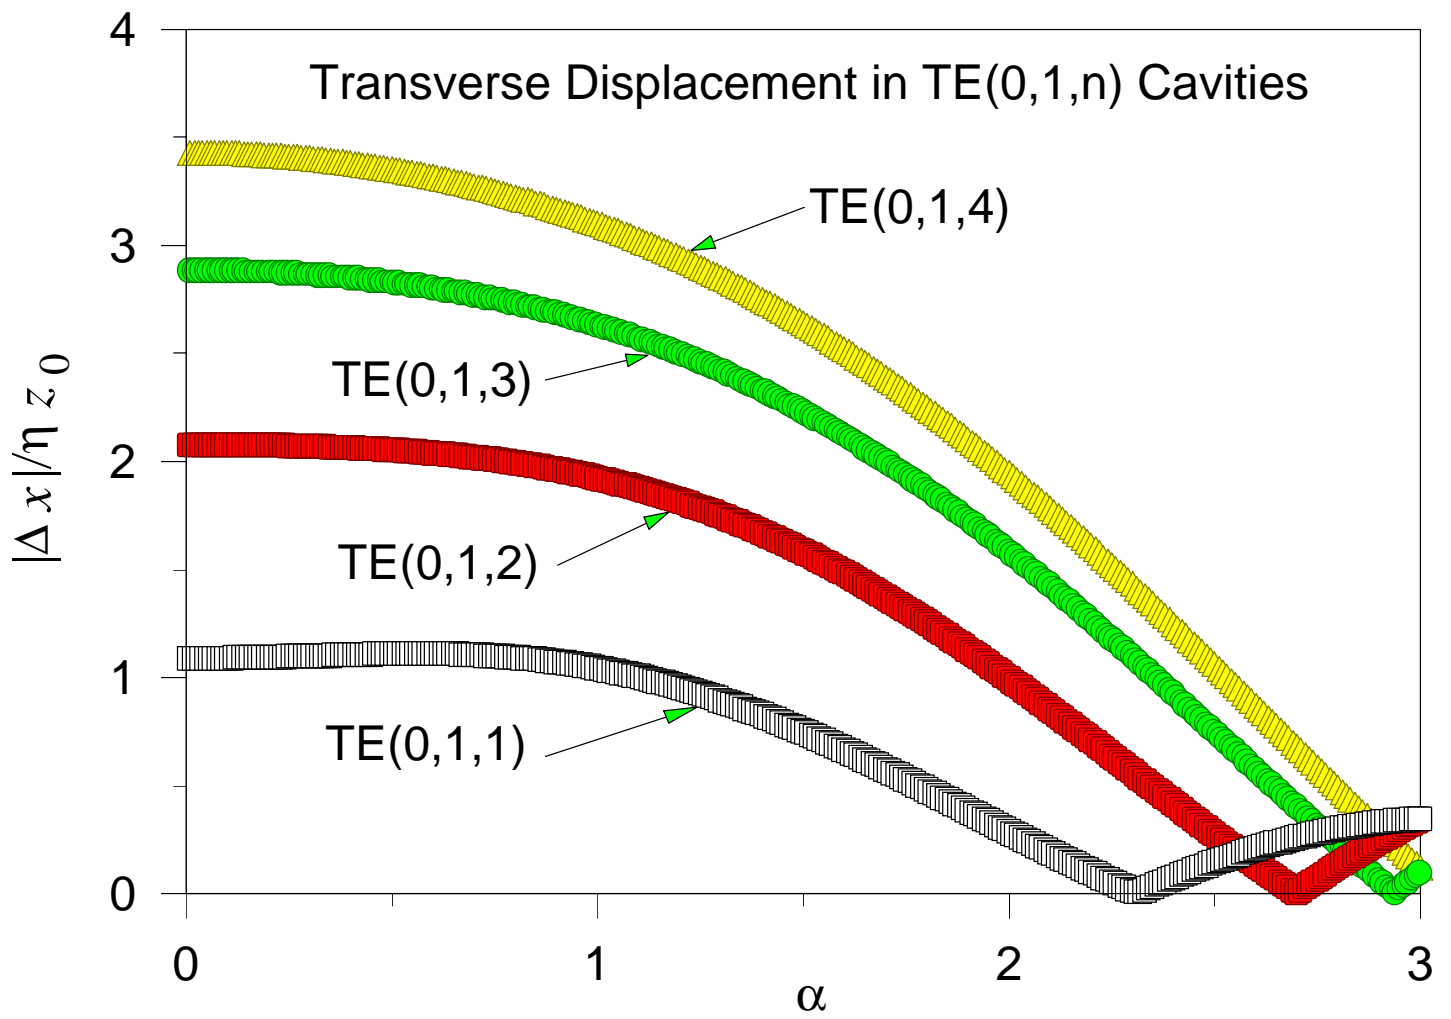

for $\omega = 2\pi 800$ MHz and $E_0 = 40$ MV/m.

$$\text{Dispersion relation: } \frac{\omega}{c} = \sqrt{n^2 + \alpha^2} \frac{\pi}{a}.$$

Transverse displacement across the cavity:

$$\frac{\Delta x}{\eta z_0} \approx \frac{2\gamma\sqrt{1 + (\alpha/n)^2}}{1 + (\gamma\alpha/n)^2} f\left(\frac{\sqrt{n^2 + \alpha^2}\pi}{2\beta_z}\right),$$

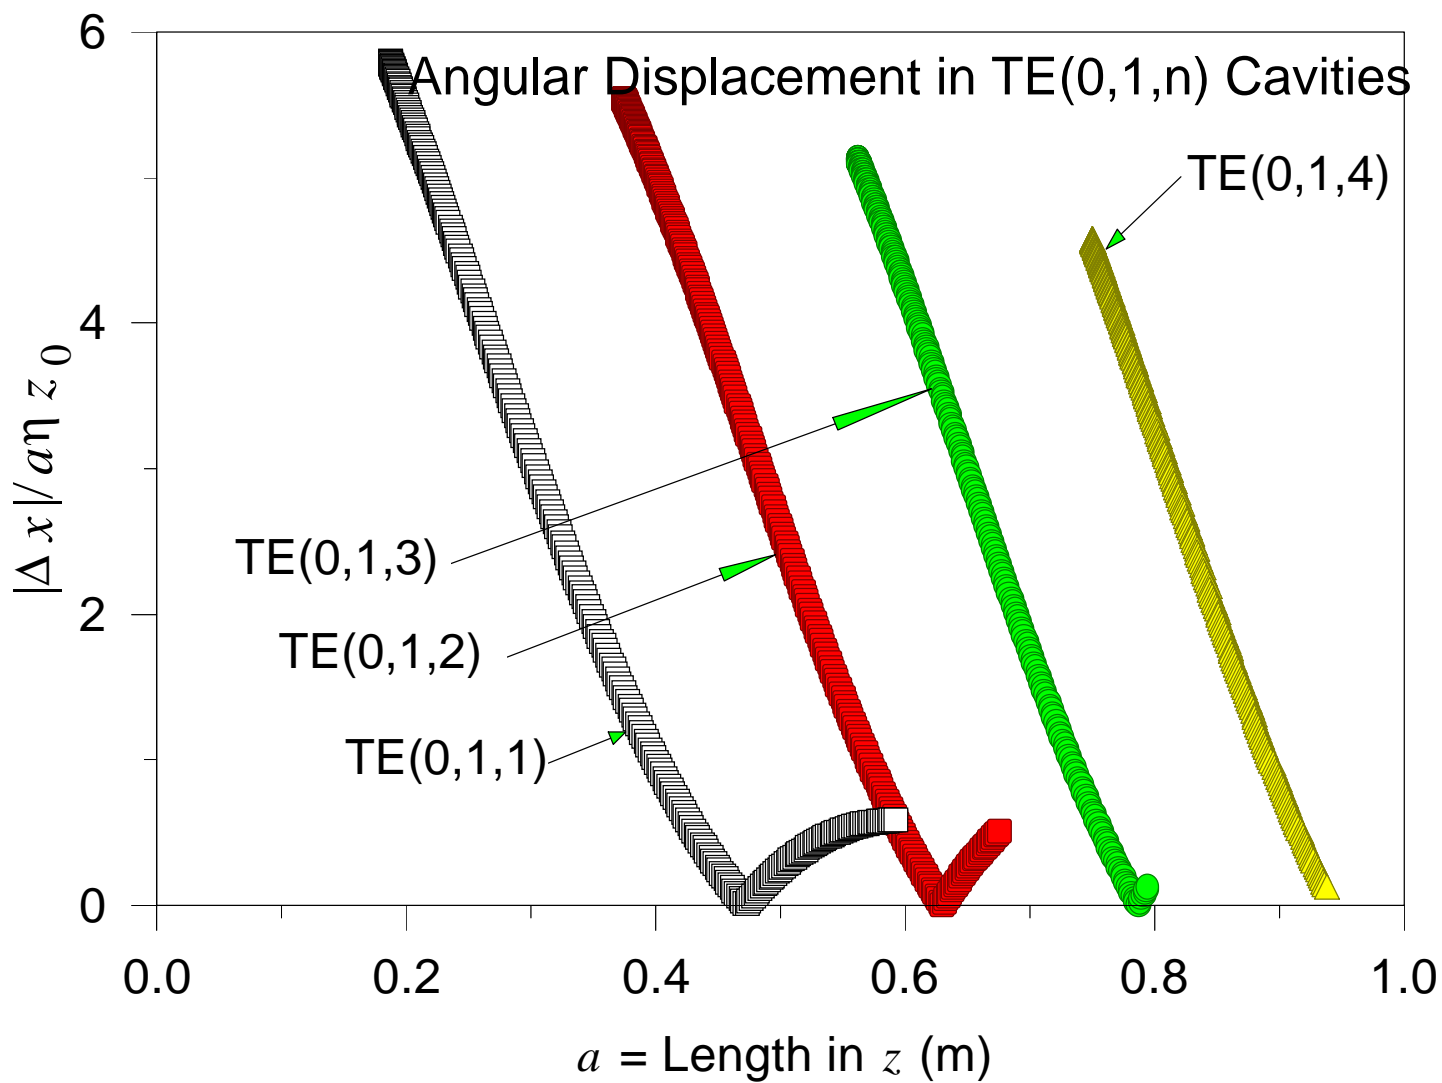

$$\text{where } f = \begin{cases} \cos, & n \text{ odd,} \\ \sin, & n \text{ even.} \end{cases}$$

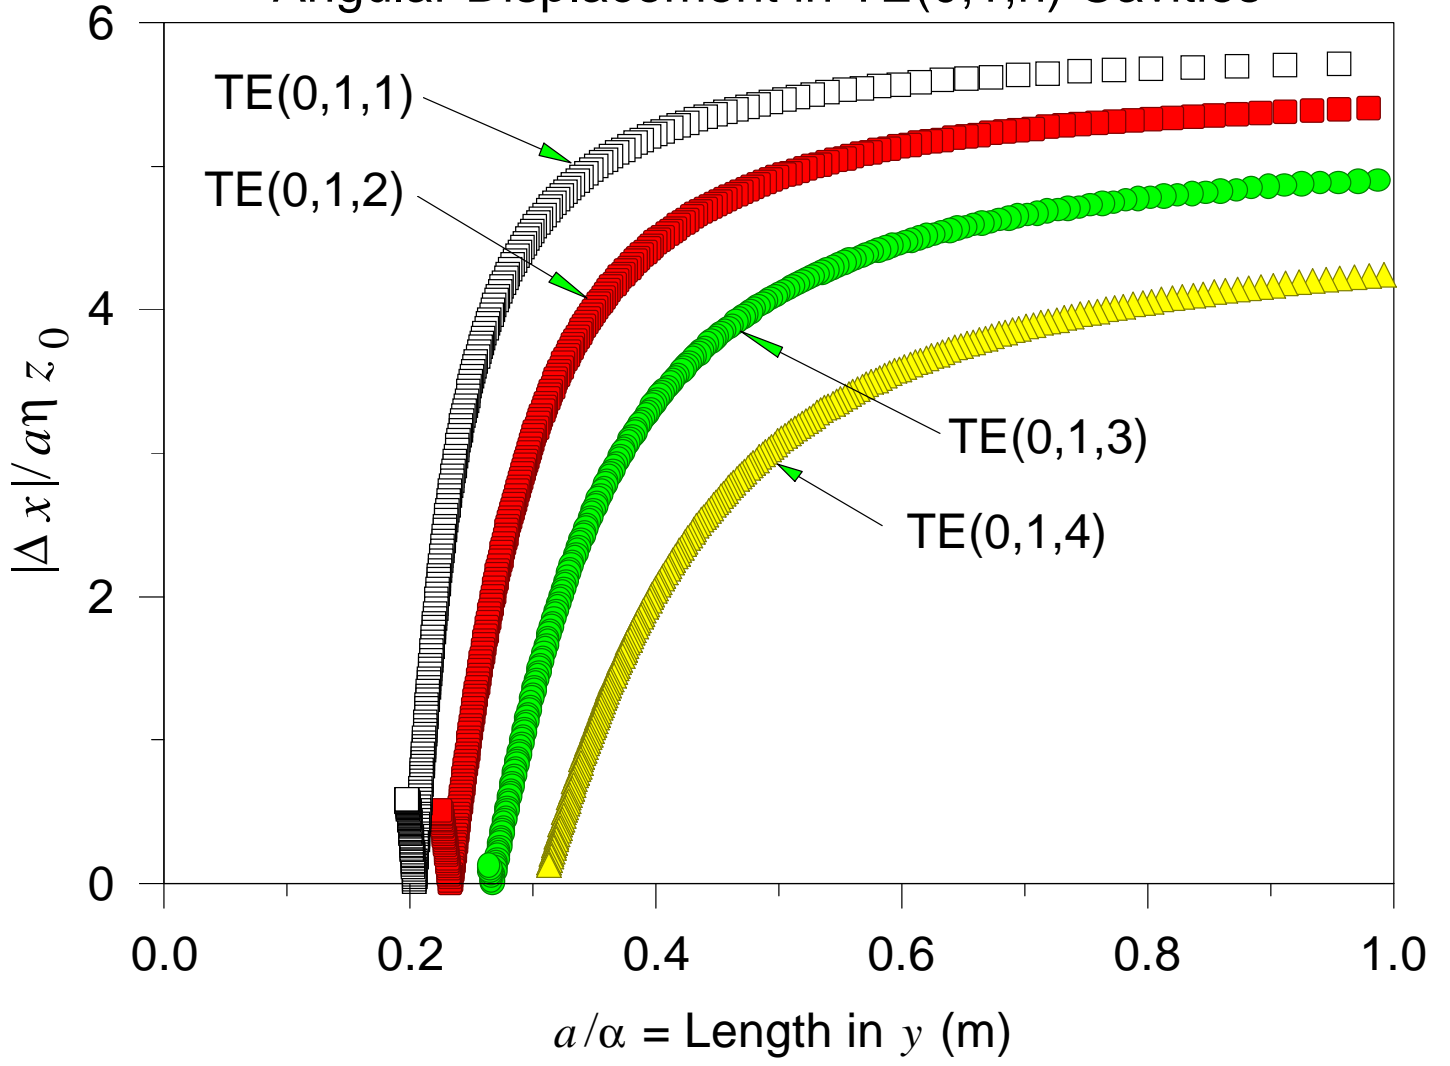

Multiple scattering will limit accuracy of Δx Measurement.

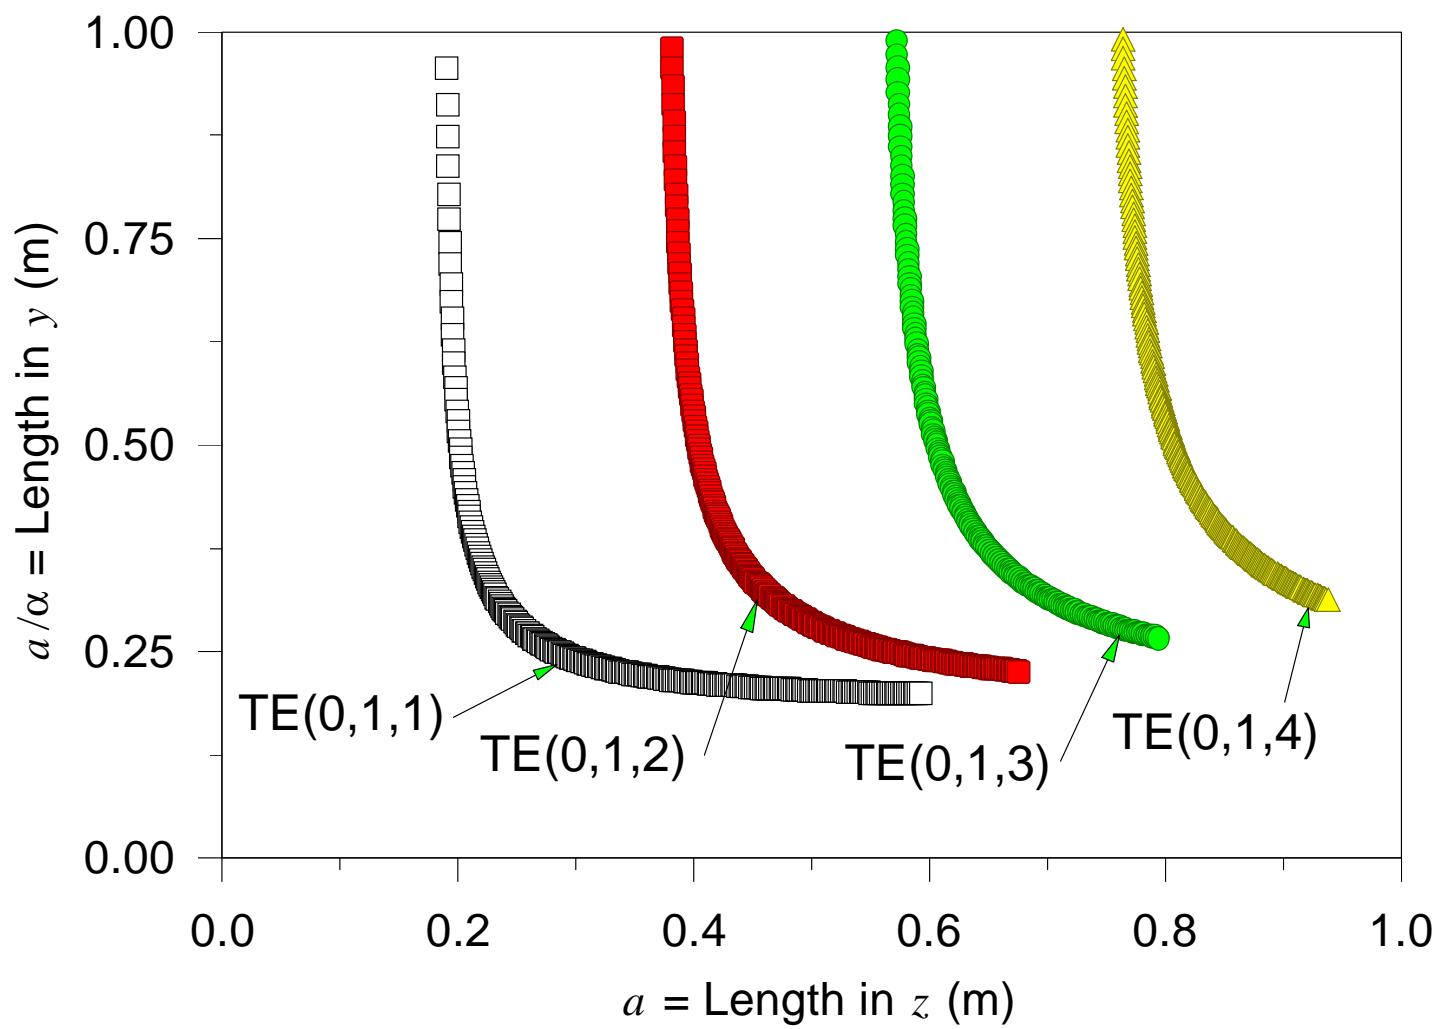

\Rightarrow angular displacement $\Delta x/a$ is figure of merit.

Angular Displacement in TE(0,1,n) Cavities

Example of TE_{0,1,1} Cavity

$$a = 20 \text{ cm}, \alpha = 0.37, a/\alpha = 54 \text{ cm}, \nu = 800 \text{ MHz},$$

$$E_0 = 40 \text{ MV/m}, \eta = 0.0223,$$

$$P = 165 \text{ MeV/c}, \gamma = 1.85, \beta_z = 0.85.$$

$$|\Delta x| = 6.2[\mu\text{m}] \left[\frac{\Delta t}{1 \text{ ps}} \right],$$

$$\frac{|\Delta x|}{a} = 30[\mu\text{rad}] \left[\frac{\Delta t}{1 \text{ ps}} \right].$$

If $\sigma_{D,t} = \sigma_t = 40 \text{ ps}$, then need

$$X_0 < \left(\frac{0.0012 \cdot 165 \cdot 0.84}{15} \right)^2 = 0.00012 \text{ radiation lengths.}$$

Thus the entrance and exit walls of a copper RF cavity should be less than $1.7 \mu\text{m}$ thick, or less than $43 \mu\text{m}$ thick if the walls are made of beryllium.

[It does not help to use multiple cavities when multiple-scattering limited.]
